1. (a) resistors in series add to 20 Ω and current is 0.60 A

__accept__ potential divider stated __or__ formula

B1

so p.d. across XY is 0.60 × 12 (= 7.2 V)

gives (12 /20) × 12 V (= 7.2)V

B1

(b) (i) the resistance of the LDR decreases

M1

(so total resistance in circuit decreases) and current increases

A1

(ii) resistance of LDR and 12 Ω (in parallel)/across **XY** decreases

B1

so has smaller share of supply p.d. (and p.d. across XY falls)

__alternative__ I increases so p.d. across 8.0 Ω increases; so p.d. across __XY__ falls

B1
