PAPER 63

THE STANDARD MODEL

Attempt **THREE** questions.

The questions are of equal weight.

You may not start to read the questions printed on the subsequent pages until instructed to do so by the Invigilator. 1 For $\phi = (\phi_1, \dots, \phi_n)$ a real multi-component scalar field, then assume a potential $V(\phi)$ is invariant under the action of a continuous group G, so that for any $g \in G$, $V(g\phi) = V(\phi)$. Suppose $\phi_0 \neq 0$ is a particular ϕ for which V has its minimum. Describe how the unbroken subgroup $H \subset G$ may be defined and explain how there are in general dimG – dimH massless modes.

[You may assume that if $V(\phi_0') = V(\phi_0)$ then $\phi_0' = g\phi_0$ for some $g \in G$.]

If G is now a local gauge group, with $A_{\mu a}$, $a = 1, \ldots, \dim G$, the corresponding gauge fields, the associated Lagrangian is

$$\mathcal{L} = \frac{1}{2} (D^{\mu} \phi)^{T} D_{\mu} \phi - \frac{1}{4} F^{\mu \nu}{}_{a} F_{\mu \nu a} - V(\phi) ,$$

where $F_{\mu\nu a}$ is the associated field strength, $D_{\mu}\phi = \partial_{\mu}\phi + gA_{\mu a}T_{a}\phi$ with T_{a} matrix generators of G, $T_{a}^{T} = -T_{a}$. Explain why we may impose the condition $\phi^{T}T_{a}\phi_{0} = 0$. Show how the gauge fields have masses defined by the matrix $g^{2}(T_{a}\phi_{0})^{T}T_{b}\phi_{0}$ and that dimG – dimH gauge fields have a non zero mass. Verify also that there are now no massless scalar fields.Briefly describe the relevance of these considerations to the standard model.

2 In the standard model the interaction of the neutral vector Z with fermion fields ψ is described by

$$\mathcal{L}_I = \frac{g}{2\cos\theta_W} J_n^\mu Z_\mu \,,$$

where the neutral current is given by

$$J_n^{\mu} = \overline{\psi} \gamma^{\mu} \left((1 - \gamma_5) T_3 - 2 \sin^2 \theta_W Q \right) \psi \,,$$

with **T** the generators of $SU(2)_T$ acting on ψ and Q the associated charge matrix. For the leptonic decay $Z \to \ell \bar{\ell}$ show that $J_n^{\mu} = \bar{\ell} \gamma^{\mu} (c_V - c_A \gamma_5) \ell$ where for $\ell = e, c_V = 2 \sin^2 \theta_W - \frac{1}{2}$, $c_A = -\frac{1}{2}$ and for $\ell = \nu_e$, $c_V = c_A = \frac{1}{2}$. Assuming

$$\langle 0|Z_{\mu}(0)|Z(p)\rangle = \epsilon_{\mu}(p), \qquad \sum_{Z \text{ spins}} \epsilon_{\mu}(p)\epsilon_{\nu}(p)^{*} = -g_{\mu\nu} + \frac{p_{\mu}p_{\nu}}{m_{Z}^{2}},$$

show that for \mathcal{M} the amplitude for $Z \to \ell \bar{\ell}$ and neglecting any lepton masses, $\sum_{\text{spins}} |\mathcal{M}|^2 = g^2 (c_V^2 + c_A^2) m_Z^2 / \cos^2 \theta_W$. Hence obtain, for $G_F / \sqrt{2} = g^2 / (8m_W^2)$,

$$\Gamma_{Z \to \ell \bar{\ell}} = \frac{G_F}{\sqrt{2}} \, \frac{m_Z^3}{6\pi} (c_V^2 + c_A^2) \, .$$

The formula for the decay width of a particle with mass m is

$$\Gamma = \frac{1}{2m} \sum_{X} (2\pi)^4 \delta^4(p - p_X) \left| \langle X | \mathcal{L}_I | p \rangle \right|^2, \quad \sum_{X} = \prod_{\text{momenta}} \int \frac{\mathrm{d}^3 p}{(2\pi)^3 2p^0} \sum_{\text{spins}} \,.$$

You may also use $\operatorname{tr}(\gamma_{\alpha}\gamma_{\beta}\gamma_{\gamma}\gamma_{\delta}) = 4(g_{\alpha\beta}g_{\gamma\delta} + g_{\alpha\delta}g_{\beta\gamma} - g_{\alpha\gamma}g_{\beta\delta}).$

3 For a hadron H of momentum $P, P^2 = M^2$, represented by the state $|P\rangle$ define

$$W^{\mu\nu}(q,P) = \frac{1}{4\pi} \sum_{X} (2\pi)^{4} \delta^{4}(P - p_{X} - q) \langle P|J^{\mu}|X \rangle \langle X|J^{\nu}|P \rangle$$
$$= \left(-g^{\mu\nu} + \frac{q^{\mu}q^{\nu}}{q^{2}}\right) W_{1} + \left(P^{\mu} - \frac{P \cdot q}{q^{2}} q^{\mu}\right) \left(P^{\nu} - \frac{P \cdot q}{q^{2}} q^{\nu}\right) W_{2}$$

where $J^{\mu} = \sum_{f} Q_{f} \overline{q}_{f} \gamma^{\mu} q_{f}$ is the electromagnetic current. If $\nu = P \cdot q$, $x = -q^{2}/2\nu$ and for $W_{1} = F_{1}(x, -q^{2})$, $\nu W_{2} = F_{2}(x, -q^{2})$ show that as $-q^{2} \to \infty$ with suitable assumptions,

$$F_1(x, -q^2) \sim \frac{1}{2} \sum_f Q_f^2 (q_f(x) + \overline{q}_f(x)), \quad F_2(x, -q^2) \sim x \sum_f Q_f^2 (q_f(x) + \overline{q}_f(x)).$$

Explain briefly why we may expect

$$\int_0^1 \mathrm{d}x \left(q_f(x) - \overline{q}_f(x) \right) = N_f \,,$$

where N_f is the number of quarks of type f in the hadron H. If only u, d quarks are relevant, so that $\overline{q}_f = 0$, and $F_2^{\text{proton}}, F_2^{\text{neutron}}$ are the functions for H corresponding to a proton, neutron what are the values of the integrals

$$\int_0^1 \frac{\mathrm{d}x}{x} F_2^{\text{proton}}(x, -q^2), \qquad \int_0^1 \frac{\mathrm{d}x}{x} F_2^{\text{neutron}}(x, -q^2),$$

as $-q^2 \to \infty$. $[\gamma^{\mu}\gamma^{\lambda}\gamma^{\nu} = g^{\mu\lambda}\gamma^{\nu} + g^{\nu\lambda}\gamma^{\mu} - g^{\mu\nu}\gamma^{\lambda} + i\epsilon^{\mu\nu\lambda\kappa}\gamma_{\kappa}\gamma_{5}.]$

4 What are the quantum numbers of the quarks and leptons for one generation in the standard model under the gauge group $SU(3)_{colour} \times SU(2)_T \times U(1)_Y$? Show that if $Q = T_3 + Y$, where **T** are the generators of $SU(2)_T$ and Y is the generator of $U(1)_Y$, then the eigenvalues of Q give the correct charges for the quarks and leptons. Due to anomalies the following constraints must be imposed,

$$\operatorname{tr}_L(T_3^2 Y) - \operatorname{tr}_R(T_3^2 Y) = 0, \qquad \operatorname{tr}_L(Y^3) - \operatorname{tr}_R(Y^3) = 0.$$

where tr_L , tr_R denote the traces for the generators acting on left handed, right handed fermion fields respectively. Show that, for the usual representations of $SU(2)_T \times U(1)_Y$, $\operatorname{tr}_R(T_3^2Y) = 0$ and also that $\operatorname{tr}_L(T_3^2Y) = \frac{1}{4}\operatorname{tr}_L(Y) = \frac{1}{4}\operatorname{tr}_L(Q)$. Hence verify that the first condition is satisfied for each generation independently. Show further that the second condition holds.

5 Show how QCD for $m_u = m_d = 0$ has a chiral $SU(2) \times SU(2)$ symmetry where if $q = \begin{pmatrix} u \\ d \end{pmatrix}$ then $q_R \to Aq_R$, $q_L \to Bq_L$ for $A, B \in SU(2)$. Let $V_{ij} = \overline{q_{Lj}}q_{Ri}$. How does this transform? If

$$\langle 0|V_{ij}|0\rangle = -v\,\delta_{ij}\,, \quad v \text{ real}, \ v > 0\,,$$

what is the symmetry reduced to? Describe in outline how this leads to massless pions. Assume that at low energies the pion fields $\boldsymbol{\pi} = (\pi_1, \pi_2, \pi_3)$ determine a matrix $U(\boldsymbol{\pi}) = \exp(i\boldsymbol{\pi}\cdot\boldsymbol{\tau}/F) \in SU(2)$ which transforms under a chiral transformation as $U(\boldsymbol{\pi}) \to AU(\boldsymbol{\pi})B^{-1}$. Show that, for up to two derivatives, there is then a unique Lagrangian for massless pions, invariant under chiral $SU(2) \times SU(2)$ symmetry, of the form

$$\mathcal{L}_{\pi} = \frac{1}{4} F^2 \operatorname{tr} \left(\partial^{\mu} U(\boldsymbol{\pi})^{\dagger} \partial_{\mu} U(\boldsymbol{\pi}) \right) = \frac{1}{2} \partial^{\mu} \boldsymbol{\pi} \cdot \partial_{\mu} \boldsymbol{\pi} + \dots$$

In QCD show that a mass term for the u, d quarks may be introduced by

$$\mathcal{L}_m = -\mathrm{tr} \left(\mathcal{M}(V+V^{\dagger}) \right), \quad \mathcal{M} = \begin{pmatrix} m_u & 0\\ 0 & m_d \end{pmatrix}, \quad m_u, m_d > 0.$$

An equivalent Lagrangian $\mathcal{L}_{\pi,m}$ for the pion fields may be constructed by letting $V \to -vU(\pi)$. By expanding $\mathcal{L}_{\pi,m}$ to second order determine the expected mass for the pions.
