## ANALYSIS OF EXPERIMENTAL DATA

## Time allowed: $\mathbf{2}$ hours

Attempt not more than FOUR questions.
All questions carry equal marks.

Throughout this examination paper, replacing a subscript by a $\bullet$ denotes that the subscript has been summed over. A bar over a quantity indicates that averaging has taken place. For example, given data $Y_{i j}$ for $i=1, \ldots, t$ and $j=1, \ldots, n$, use the notation

$$
\begin{array}{cc}
Y_{\bullet \bullet}=\sum_{j=1}^{n} Y_{i j}, & Y_{\bullet \bullet}=\sum_{i=1}^{t} \sum_{j=1}^{n} Y_{i j}, \\
\bar{Y}_{i \bullet}=\frac{1}{n} \sum_{j=1}^{n} Y_{i j}, & \text { and }
\end{array} \quad \bar{Y}_{\bullet \bullet}=\frac{1}{n t} \sum_{i=1}^{t} \sum_{j=1}^{n} Y_{i j} . ~ \$
$$

1. Consider the one-way fixed and random effects ANOVA models

$$
\begin{array}{lll}
\text { FIXED } & Y_{i j}=\mu+\alpha_{i}+\varepsilon_{i j} & \sum_{i=1}^{t} \alpha_{i}=0, \\
\text { RANDOM } & Y_{i j}=\mu+A_{i}+\varepsilon_{i j} & A_{i} \text { i.i.d. } N\left(0, \sigma_{A}^{2}\right),
\end{array}
$$

for $i=1, \ldots, t$ and $j=1, \ldots, n$. Let the total number of observations be $N=n t$. Here $Y_{i j}$ is the $j$ th observation in the $i$ th group, the $\varepsilon_{i j}$ are independently $N\left(0, \sigma^{2}\right)$ distributed (independent of the $A_{i}$ ) and represent random variation, and the $\alpha_{i}$ and $A_{i}$ represent effects of the treatment groups.
(a) Briefly explain when the fixed and random effects models are appropriate. In particular, under what circumstances would you choose to use each model?
In a one-way ANOVA, we wish to test the null hypothesis that there are no treatment effects against the alternative that the treatment affects the mean response. Write down null and alternative hypotheses for the fixed and random effects models above. Your hypotheses should be in terms of the model parameters $\left\{\alpha_{i}\right\}$ and $\sigma_{A}^{2}$.
(b) Three experiments were carried out to study the yield of wheat in different treatment groups. For each of the following descriptions of the treatment groups, say whether a fixed or random effects model would be appropriate. Justify your choice in each case.
(i) To examine the effects of different fertilisers, each group was given a different brand of fertiliser.
(ii) All groups were given the same brand of fertiliser, but from different production batches, to check the consistency of the results from experiment (i).
(iii) In order to determine the best dosage of fertiliser to maximise cost-effectiveness, each group was given a different selected dose of fertiliser.
(c) Define the treatment and error sums of squares to be $S S_{T}=\sum_{i=1}^{t} n\left(\bar{Y}_{i \bullet}-\bar{Y}_{\bullet \bullet}\right)^{2}$ and $S S_{E}=\sum_{i=1}^{t} \sum_{j=1}^{n}\left(Y_{i j}-\bar{Y}_{i \bullet}\right)^{2}$ and the corresponding mean squares to be $M S_{T}=$ $S S_{T} /(t-1)$ and $M S_{E}=S S_{E} /(N-t)$. We estimate $\mu$ by the least squares estimator $\widehat{\mu}=\bar{Y}_{\bullet}$ and $\sigma^{2}$ by the unbiased estimator $\widehat{\sigma}^{2}=M S_{E}$.
(i) In the fixed effects model, the $\alpha_{i}$ are estimated by $\widehat{\alpha}_{i}=\bar{Y}_{\bullet \bullet}-\bar{Y}_{\bullet \bullet}$ for $i=1, \ldots, t$. Show that the $\widehat{\alpha}_{i}$ are unbiased estimators.
(ii) For the random effects model, $E\left(M S_{T}\right)=n \sigma_{A}^{2}+\sigma^{2}$. Construct an unbiased estimator for $\sigma_{A}^{2}$ and show that your estimator is unbiased.
(d) A national supermarket chain wanted to determine whether typical sales were different in different stores. Five stores were chosen randomly from across the country. In each store, the values of eleven randomly chosen trolley loads of shopping were recorded.
Given that the sums of squares calculated from these data were $S S_{T}=541.17$ and $S S_{E}=933.14$, construct an ANOVA table to test the null hypothesis that there is no significant difference in the mean spend in the stores. Assuming that a random effects model is appropriate, estimate $\sigma^{2}$ and $\sigma_{A}^{2}$. Comment on your findings.
2. Consider the one-way fixed effects ANOVA model

$$
Y_{i j}=\mu+\alpha_{i}+\varepsilon_{i j} \quad i=1, \ldots, t ; \quad j=1, \ldots, n ; \quad \varepsilon_{i j} \text { i.i.d. } N\left(0, \sigma^{2}\right)
$$

If the ANOVA null hypothesis $H_{0}: \alpha_{i}=0$ for all $i$ is rejected, we know that some treatments are not equivalent. One way to investigate which treatments are significantly different is by using contrasts. Define a contrast to be a linear combination $C=\sum_{i} c_{i} Y_{i} \bullet$ with $\sum_{i} c_{i}=0$. We use $C$ to test the hypothesis $H_{0}: \sum_{i} c_{i} \mu_{i}=0$ against $H_{A}: \sum_{i} c_{i} \mu_{i} \neq 0$, where $\mu_{i}=\mu+\alpha_{i}$.
(a) Let the sum of squares for the contrast $C$ be

$$
S S_{C}=\frac{C^{2}}{n \sum_{i} c_{i}^{2}}
$$

Show that, under $H_{0}: \sum_{i} c_{i} \mu_{i}=0$, the distribution of $S S_{C}$ is given by $S S_{C} / \sigma^{2} \sim \chi_{1}^{2}$.
Hint: First write down the distribution of $Y_{i \bullet}$ and use this to find the distribution of $C$. Write down the expectation and variance of this distribution when $H_{0}$ is true. Then use the fact that if $Z \sim N(0,1)$, we have $Z^{2} \sim \chi_{1}^{2}$ by definition.
(b) A manufacturer needs to outsource the production of a chemical. Before deciding on a supplier, the manufacturer asks four laboratories to manufacture five batches each. A numeric measurement of quality is assigned to each batch and these values are shown below. Given that $\sum_{i j} y_{i j}^{2}=319.9826$ and $\sum_{i} y_{i \bullet}^{2}=1599.53$, construct an ANOVA table and test the null hypothesis of no difference between laboratories. Comment on your results.

Quality measurements on batches of chemicals

| Laboratory | Quality measurements |  |  |  |  | $y_{i}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 4.13 | 4.07 | 4.04 | 4.07 | 4.05 | 20.36 |
| 2 | 3.86 | 3.85 | 4.08 | 4.11 | 4.08 | 19.98 |
| 3 | 4.00 | 4.02 | 4.01 | 4.01 | 4.04 | 20.08 |
| 4 | 3.88 | 3.89 | 3.91 | 3.96 | 3.92 | 19.56 |

(c) Before gathering the data in part (b), prior experience suggested that laboratories one and three would be equivalent, as would laboratories two and four, although laboratories one and three would be different to laboratories two and four.
Construct a set of contrasts to test whether these suppositions are correct. Carry out your tests using a $5 \%$ significance level. Comment on your findings.

3．Consider the two－way fixed effects ANOVA model $Y_{i j k}=\mu+\alpha_{i}+\beta_{j}+\gamma_{i j}+\varepsilon_{i j k}$ for $i=1, \ldots, a, j=1, \ldots, b$ and $k=1, \ldots, n$ ．Here，$\alpha_{i}$ represents level $i$ of factor $\mathrm{A}, \beta_{j}$ represents level $\mathbf{j}$ of factor $\mathbf{B}, \gamma_{i j}$ represents the interaction between levels $i$ and $j$ of factors A and B respectively，and the $\varepsilon_{i j k}$ are independently $N\left(0, \sigma^{2}\right)$ distributed representing random variation．
（a）List a set of constraints commonly applied to the parameters $\left\{\alpha_{i}\right\},\left\{\beta_{j}\right\}$ and $\left\{\gamma_{i j}\right\}$ ．With reference to the number of cells or groups in the data，explain why these（or other） constraints must be applied．
（b）By minimising a suitable sum of squares，show that $\mu$ is estimated by $\widehat{\mu}=\bar{Y}_{\ldots}$ ．．and derive least squares estimates $\left\{\widehat{\alpha_{i}}\right\}$ of the parameters $\left\{\alpha_{i}\right\}$ for $i=1, \ldots, a$ ．Write down without proof least squares estimates of the parameters $\left\{\beta_{j}\right\}$ and $\left\{\gamma_{i j}\right\}$ ．
（c）A study was carried out to assess the performance of four different designs of air－ conditioning unit in different regions of the U．S．A．Two air conditioning units of each design were installed in each region，thus obtaining a pair of observations for each com－ bination of region and design．The time to failure of the units in months are given below．Cell sums $y_{i j \bullet}$ ，row sums $y_{i \bullet \bullet}$ ，column sums $y_{\bullet j \bullet}$ and the grand total $y_{\bullet \bullet \bullet}$ are also provided，all in italic type．

## Time to failure of air－conditioning units

| Region | Design |  |  |  |  |  |  |  |  |  |  |  | $y_{i \bullet \bullet}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | A |  |  | B |  |  | C |  |  | D |  |  |  |
|  |  |  | $y_{i 1}$ • |  |  | $y_{i 2}$ 。 |  |  | $y_{i 3}$ 。 | D |  | $y_{i 4}$ 。 |  |
| Northeast | 58 | 49 | 107 | 35 | 24 | 59 | 72 | 60 | 132 | 61 | 64 | 125 | 423 |
| Southeast | 40 | 38 | 78 | 18 | 22 | 40 | 54 | 64 | 118 | 38 | 50 | 88 | 324 |
| Northwest | 63 | 59 | 122 | 44 | 16 | 60 | 81 | 60 | 141 | 52 | 48 | 100 | 423 |
| Southwest | 36 | 29 | 65 | 9 | 13 | 22 | 47 | 52 | 99 | 30 | 41 | 71 | 257 |
| $y_{\bullet} \cdot$ |  |  | 372 |  |  | 181 |  |  | 490 |  |  | 384 | 1427 |

Analysing the data in $R$ produced the following edited output，where $t \mathrm{f} \mathrm{f}$ refers to the time to failure．

```
> aircon.lm = lm(ttf ~ region * design)
> anova(aircon.lm)
\begin{tabular}{lrrrrrr} 
& Df Sum Sq Mean Sq & F value & Pr \((>F)\) \\
region & a & 2475.1 & b & 12.6502 & 0.0001714 \\
design & 3 & c & 2067.4 & 31.7002 & \(5.768 e-07\) \\
region：design & 9 & 310.8 & 34.5 & d & 0.8325323 \\
Residuals & 16 & 1043.5 & 65.2 & &
\end{tabular}
```

Fill in the missing values indicated by the letters a to d and interpret the resulting table． For any terms which you believe should be included in the model，estimate the model parameters．
Given your parameter estimates，what are the predicted times to failure for each type of air conditioning unit when used in the northeastern U．S．A？
4. Consider the fixed effects nested design model

$$
Y_{i j k}=\mu+\alpha_{i}+\beta_{j(i)}+\varepsilon_{i j k}
$$

for $i=1, \ldots, a, j=1, \ldots, b$ and $k=1, \ldots, n$. Here, $\alpha_{i}$ represents level $i$ of factor A, $\beta_{j(i)}$ represents level j of factor B nested within level $i$ of factor A , and the $\varepsilon_{i j k}$ are independently $N\left(0, \sigma^{2}\right)$ distributed representing random variation. Assume that $\sum_{i} \alpha_{i}=0$ and $\sum_{j} \beta_{j(i)}=0$ for each $i=1, \ldots, a$.
(a) Let the total sum of squares and sums of squares for main groups, sub groups and errors be defined by

$$
\begin{aligned}
S S_{T O T}=\sum_{i=1}^{a} \sum_{j=1}^{b} \sum_{k=1}^{n}\left(Y_{i j k}-\bar{Y}_{\bullet \bullet}\right)^{2}, & S S_{M G}=b n \sum_{i=1}^{a}\left(\bar{Y}_{i \bullet \bullet}-\bar{Y}_{\bullet \bullet \bullet}\right)^{2}, \\
S S_{S G}=n \sum_{i=1}^{a} \sum_{j=1}^{b}\left(\bar{Y}_{i j \bullet}-\bar{Y}_{i \bullet \bullet}\right)^{2} & \text { and }
\end{aligned} \quad S S_{E}=\sum_{i=1}^{a} \sum_{j=1}^{b} \sum_{k=1}^{n}\left(Y_{i j k}-\bar{Y}_{i j \bullet}\right)^{2} . ~ \$
$$

Show that $S S_{T O T}=S S_{M G}+S S_{S G}+S S_{E}$. Explain what each of the sums of squares quantities represents.
(b) Show that the error sum of squares can be written as

$$
\begin{equation*}
S S_{E}=\sum_{i=1}^{a} \sum_{j=1}^{b} \sum_{k=1}^{n} Y_{i j k}^{2}-n \sum_{i=1}^{a} \sum_{j=1}^{b} \bar{Y}_{i j \bullet}^{2} . \tag{1}
\end{equation*}
$$

Given that $E\left(Y_{i j k}^{2}\right)=\left(\mu+\alpha_{i}+\beta_{j(i)}\right)^{2}+\sigma^{2}$ and $E\left(\bar{Y}_{i j \bullet}^{2}\right)=\left(\mu+\alpha_{i}+\beta_{j(i)}\right)^{2}+\sigma^{2} / n$, use equation (1) to show that $E\left(S S_{E}\right)=a b(n-1) \sigma^{2}$.
(c) A process engineer was testing the yield of a product manufactured on three machines, each of which has three stations at which the product is manufactured. An experiment was conducted where three observations were taken from each station giving the yields below.

## Process yields

| Station: | Machine 1 |  |  | Machine 2 |  |  | Machine 3 |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 1 | 2 | 3 | 1 | 2 | 3 |
|  | 34.1 | 33.7 | 36.2 | 31.1 | 33.1 | 32.8 | 32.9 | 33.8 | 33.6 |
|  | 30.3 | 34.9 | 36.8 | 33.5 | 34.7 | 35.1 | 33.0 | 33.4 | 32.8 |
|  | 31.6 | 35.0 | 37.1 | 34.0 | 33.9 | 34.3 | 33.1 | 32.8 | 31.7 |
| $y_{i j} \bullet$ | 96.0 | 103.6 | 110.1 | 98.6 | 101.7 | 102.2 | 99.0 | 100.0 | 98.1 |
| $y_{i}$ • |  | 309.7 |  |  | 302.5 |  |  | 297.1 |  |

Explain why a nested model is appropriate to analyse these data.
Given that $\sum_{i, j, k} y_{i j k}^{2}=30688.51, \sum_{i j} y_{i j \bullet}^{2}=92005.27$ and $\sum_{i} y_{i \bullet \bullet}^{2}=275688.75$, construct an ANOVA table to determine whether the machines or stations have any significant effect on the yield of the process. Comment on your results.
5. A continuous response variable $Y$ may be modelled in terms of a continuous predictor variable $X$ by the centred simple linear regression model $Y=\alpha+\beta(X-\bar{X})+\varepsilon$ where $\varepsilon \sim N\left(0, \sigma^{2}\right)$. Given data $\left\{\left(X_{i}, Y_{i}\right) ; i=1, \ldots, n\right\}$, least squares estimates of $\alpha$ and $\beta$ are $\widehat{\alpha}=\bar{Y}$ and $\widehat{\beta}=S_{X Y} / S_{X X}$, where $S_{X Y}=\sum_{i}\left(X_{i}-\bar{X}\right)\left(Y_{i}-\bar{Y}\right)$ and $S_{X X}=\sum_{i}\left(X_{i}-\bar{X}\right)^{2}$. Define the residual mean square to be $M S_{R E S}=(n-2)^{-1} \sum_{i}\left[Y_{i}-\widehat{\alpha}-\widehat{\beta}\left(X_{i}-\bar{X}\right)\right]^{2}$.
(a) An alternative matrix form for the centred simple linear regression model is $\boldsymbol{y}=\boldsymbol{X} \boldsymbol{\theta}+$ $\boldsymbol{\varepsilon}$. In this matrix form, $\boldsymbol{y}$ and $\boldsymbol{\varepsilon}$ are vectors of length $n, \boldsymbol{X}$ is an $n \times 2$ matrix and $\boldsymbol{\theta}$ is a vector of length 2 . Explain how to construct $\boldsymbol{y}, \boldsymbol{X}, \boldsymbol{\theta}$ and $\varepsilon$.
Show that $S_{X Y}$ can be written as $S_{X Y}=\sum_{i}\left(X_{i}-\bar{X}\right) Y_{i}$.
The estimate of the parameter vector $\boldsymbol{\theta}$ is $\widehat{\boldsymbol{\theta}}=\left(\boldsymbol{X}^{T} \boldsymbol{X}\right)^{-1} \boldsymbol{X}^{T} \boldsymbol{y}$. Show by substituting $\boldsymbol{X}$ and $\boldsymbol{y}$ that this gives the least squares estimates $\widehat{\alpha}$ and $\widehat{\beta}$.
(b) Show that $\operatorname{var}(\widehat{\boldsymbol{\theta}})=\left[\begin{array}{cc}\sigma^{2} / n & 0 \\ 0 & S_{X X} / n\end{array}\right]$.

Hint: You may use the facts that $\operatorname{var}(\widehat{\boldsymbol{\theta}})=E\left\{(\widehat{\boldsymbol{\theta}}-\boldsymbol{\theta})(\widehat{\boldsymbol{\theta}}-\boldsymbol{\theta})^{T}\right\}$ and $E\left(\boldsymbol{\varepsilon} \varepsilon^{T}\right)=\sigma^{2} \boldsymbol{I}$, where $I$ is the identity matrix.
(c) The winning time in minutes ( $y$ ) taken to run 34 Scottish hill races in 1984 were recorded, along with the length of the races in miles $(x)$. Given that $\bar{x}=7.66, \bar{y}=57.26$, $S_{x x}=1016.360, S_{x y}=8739.455$, and $M S_{R E S}=298$, fit a linear regression model predicting winning time from the length of the race. What would you expect the winning time to be for the Knock Hill race, which is three miles in length?
A normal QQ plot of the residuals and a plot of the residuals against the times are shown below. Comment on the implications of these plots. If they reveal any problems with the linear regression, indicate how you might remedy these problems.
Construct a $95 \%$ confidence interval for the expected time taken to complete a race of zero distance. Comment on any implications of your confidence interval.

## Percentage Points of the $\chi^{2}$-Distribution

This table gives the percentage points $\chi_{\nu}^{2}(P)$ for various values of $P$ and degrees of freedom $\nu$, as indicated by the figure to the right.

If $X$ is a variable distributed as $\chi^{2}$ with $\nu$ degrees of freedom, $P / 100$ is the probability that $X \geq \chi_{\nu}^{2}(P)$.

For $\nu>100, \sqrt{2 X}$ is approximately normally distributed with mean $\sqrt{2 \nu-1}$ and unit variance.

| $\nu$ | Percentage points $P$ |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 99.95 | 99.9 | 99.5 | 99 | 97.5 | 95 | 90 | 80 |
| 1 | $3.9 \mathrm{e}-07$ | 1.6e-06 | 3.9e-05 | 1.6e-04 | 9.8e-04 | $3.9 \mathrm{e}-03$ | 1.6e-02 | 6.4e-02 |
| 2 | 0.001 | 0.002 | 0.010 | 0.020 | 0.051 | 0.103 | 0.211 | 0.446 |

## Percentage Points of the $\boldsymbol{t}$-Distribution

This table gives the percentage points $t_{\nu}(P)$ for various values of $P$ and degrees of freedom $\nu$, as indicated by the figure to the right.

The lower percentage points are given by symmetry as $-t_{u}(P)$, and the probability that $|t| \geq$ $t_{u}(P)$ is $2 P / 100$.

## MATH2730

## 5 Percent Points of the $\boldsymbol{F}$-Distribution

This table gives the percentage points $F_{\nu_{1}, \nu_{2}}(P)$ for $P=0.05$ and degrees of freedom $\nu_{1}, \nu_{2}$, as indicated by the figure to the right.

The lower percentage points, that is the values $F_{\nu_{1}, \nu_{2}}^{\prime}(P)$ such that the probability that $F \leq$ $F_{\nu_{1}, \nu_{2}}^{\prime}(P)$ is equal to $P / 100$, may be found using the formula

$$
F_{\nu_{1}, \nu_{2}}^{\prime}(P)=1 / F_{\nu_{1}, \nu_{2}}(P)
$$
