## FUNDAMENTALS OF CHEMISTRY 1B (CHEM1002) - November 2005

## 2005-N-2

- Both have hexagonal layers of metal atoms.

Both have coordination numbers of 12 .
Both fill $74 \%$ of the space in a unit cell.
The layer stacking sequence is different:
hcp: ABABAB
сср: ABCABC

- $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}(\mathrm{s}) \rightleftharpoons 5 \mathrm{Ca}^{2+}(\mathrm{aq})+3 \mathrm{PO}_{4}^{3-}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$

Both $\mathrm{PO}_{4}{ }^{3-}(\mathrm{aq})$ and $\mathrm{OH}^{-}(\mathrm{aq})$ ions react with $\mathrm{H}^{+}(\mathrm{aq})$ and are therefore removed from the above equilibrium. The reaction therefore moves to the right and more hydroxyapatite dissolves to re-establish equilibrium and tooth decay increases.

Fluoride ion in the water promotes the formation of fluoroapatite, $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}$. This compound is less soluble in water than apatite. Also $\mathrm{F}^{-}(\mathrm{aq})$ is a weaker base than $\mathrm{OH}^{-}$ (aq), so it is less soluble in acid than the hydroxy analogue.

2005-N-3

- $\quad\left[\mathrm{Ni}(\mathrm{en})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$

N and O
$3 d^{8}$

- $\quad$ A strong acid dissociates $100 \%$ in water: $\mathrm{HA}(\mathrm{aq}) \rightarrow \mathrm{H}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq})$

A weak acid does not dissociate $100 \%$ in water: $\mathrm{HA}(\mathrm{aq}) \rightleftharpoons \mathrm{H}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq})$
The \% ionisation increases.
Le Chatelier’s principle.
$K_{\mathrm{a}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ Dilution affects all terms in this equation, causing decrease in $Q$. The reaction will therefore move to the right, i.e. \% ionisation will increase.

2005-N-4

- The two molecules have to be aligned or oriented correctly.

They need to collide with sufficient energy to overcome activation barrier.
From Arrhenius equation, $k=A e^{-E_{\mathrm{a}} R T}$, the larger the activation energy, $E_{\mathrm{a}}$, the smaller the rate constant, $k$. i.e. higher $E_{\mathrm{a}}$ results in slower reaction rate.
$152 \mathrm{~kJ} \mathrm{~mol}^{-1}$
