Answer any THREE questions.

1. (a) Give the syntax for the untyped lambda calculus with operators and constants.

[8]

(b) Explain in detail how a lambda-calculus program is evaluated, including an explanation of the term “reducible expression”.

[11]

(c) Give a detailed explanation of the operation of the four reduction rules that can be used to evaluate an expression in the untyped lambda calculus with operators and constants.

[8]

(d) Explain how name clashes affect the evaluation of lambda expressions. Explain with an example the free-variable-capture problem and how it can be solved.

2. (a) Give a Miranda algebraic type definition for a binary tree called **numchartree** that contains one data value (only) in each node, and where that data value can be either a number or a character (but no other type). [4]

(b) Give the Miranda function definition, including its type, for a function called **insertnum** which inserts a number into a **numchartree** such that the tree contains only numbers and such that the numbers in the tree are *sorted*; i.e. for each node containing value **v**, all the numbers held in its right subtree are greater than or equal to **v**, and all the numbers held in its left subtree are less than **v**. [8]

(c) Modify your definition for **insertnum** so that when a new number is added to a **numchartree** the tree remains *balanced*. A balanced tree is one where, for each node in the tree, the numbers of nodes in its two subtrees differ by no more than one - i.e. if the number of nodes in the left subtree is x, and the number of nodes in the right subtree is y, then

```
abs (x-y) <= 1
```

3. You are given the following function definitions:

```
cancel x y = x

swap f x y = f y x

nil y = error "cannot take head or tail of empty list"

cons a b f = f a b

head x = x cancel

tail x = x (swap cancel)
```

(a) Use hand evaluation to demonstrate the following two equalities:

```
head (cons a b) = a

tail (cons a b) = b
```

[4]

(b) Use hand evaluation to demonstrate the following equality:

```
head (tail (cons a (cons b c))) = b
```

[8]

(c) Explain why the following function definition is wrong:

```
newmap f        nil = nil
newmap f (cons a b) = cons (f a) (newmap f b)
```

[6]

(d) Suggest a correct definition for the function **newmap** that maps a function over the elements of the "cons" as defined in this question (above). Do **not** atempt to give the type for **newmap**.

4. (a) Explain how a tree of binary application nodes can be used to represent a functional program and how this representation naturally supports both curried function definitions and can be extended to support recursive functions.

[6]

(b) Give a brief overview of the structure and high-level operation of a parallel functional programming system.

[8]

(c) Explain how the Four Stroke Reduction Engine evaluates applications of (i) user functions, and (ii) built-in operators.

[13]

(d) In the Four Stroke Reduction Engine, how do parallel tasks communicate with each other (for example, if one task is evaluating a subexpression whose result is required by another task)?

[6]

5. (a) State briefly what garbage collection is and why it is necessary for both Miranda and Java. Give a pictorial example of the creation of garbage in a graph reduction system.

[8]

(b) Describe briefly the operation of three different garbage-collection techniques and compare their advantages and disadvantages.

[15]

(c) What is fragmentation and how can it be cured? Your explanation should make reference to the three garbage collectors described in your answer to part (b) of this question.
